To my family, whose immense support helped me publish this work.

Acknowledgements

This dissertation was written during my time as a research associate at the Department of Fluid Mechanics of the University of Wuppertal.

First and foremost, I express my deepest gratitude to Prof. Dr.-Ing. habil. Uwe Janoske, whose continuous guidance and outstanding support made this work possible. I am ever grateful to be his student, which helped me learn valuable life lessons. Sincere thanks to Prof. Dr.-Ing. Dietmar Tutsch for his time and effort in reviewing this work and providing constant input during project meetings. My hearty thanks to Dr.-Ing. Roman Düssel, who has been a constant guide in the complex topic of aluminium production and TRIMET Aluminium SE for providing me with the opportunity and support. For the financial support I received during my research work, the European Regional Development Fund and the state of North Rhine-Westphalia have my sincere gratitude.

Special thanks to my longtime friend and colleague, Dr.-Ing. Chethan Mohankumar, for the insightful discussions during my research work. The wholesome support from Dipl.-Ing. Wolfgang Rupp and Dr.-Ing. Uwe Fechter is warmly appreciated. I am grateful to my project team comprising Roman Gutt, Hendrik Gesell and Dr.-Ing. Alessandro Cubeddu, with whom the technical discussions over espresso helped me streamline my work. Sincere thanks to Birger Thünchen for his support in the laboratory. I kindly appreciate the contributions of Bo Jäger and Matthias Wrobel to the experimental aspects of this work. My gratitude to all my colleagues at the Department of Fluid Mechanics, Wuppertal, who made this journey possible.

I am eternally grateful to my wife, Sindhu, for the unconditional support and motivation till the end. I am forever indebted to my mother, Varalakshmi, and my father, Nagendra, who inspired me in all good things. Many thanks to my family and friends who have provided me with support and love.

Abstract

Aluminium is one of the most widely used metals in the world. The production of primary aluminium is a complex process with high energy requirements. Climate goals have steered many countries to shift towards renewable sources for electricity production, increasing the energy costs. The transition necessitates smelters to augment the production efficiency to produce aluminium at competitive prices. Additionally, the fluctuations in the electricity price in the energy market could be utilized to benefit the smelter by achieving flexibility in the production process. A detailed understanding of the cell behaviour is necessary to realize these objectives. The corrosive environment and high temperatures inside the Hall-Héroult cell, as well as the high magnetic fields, significantly reduces the observability of the process, as measurement-based research is significantly restricted. A numerical model, on the other hand, provides several advantages to study the influence of various cell parameters without affecting industrial production.

The thermal balance of the cell is critical to achieving stable and efficient production. In the present work, a numerical model in the Multi-Region framework is developed to study the electric and thermal behaviour of the cell. The numerical model is developed in OpenFOAM® 4.0, an open-source CFD toolkit.

The numerical model is validated by comparing the simulation predictions with the industrial measurements. This is followed by studying the influence of the operational parameters on the electric and thermal behaviour of the cell. The operational parameters considered in this study are the amount of aluminium and electrolyte, anode-to-cathode distance, cell current, bath composition and sidewall cooling. The influence on the cell behaviour is evaluated by analyzing the variation in the ledge thickness, the bath temperature, the ohmic voltage and the cell specific energy consumption. The results of this work provide detailed insights into the thermoelectric behaviour of the cell and identifies critical parameters, which has a high impact on the production efficiency.

Kurzfassung

Aluminium ist eines der auf der Welt am häufigsten verwendeten Metalle. Die Herstellung von Primäraluminium ist allerdings ein komplexer Prozess mit hohem Energiebedarf. Wegen der Klimaziele haben viele Länder entschieden, bei der Stromerzeugung auf erneuerbare Energien umzusteigen, was die Energiekosten steigen lässt. Um Aluminium dort weiterhin zu wettbewerbsfähigen Preisen produzieren zu können, müssen die Aluminiumhütten die Effizienz und Flexibilität der Zellen steigern. Um diese Ziele zu erreichen, ist ein detailliertes Verständnis des Verhaltens der Aluminiumzelle erforderlich. Eine korrosive Umgebung, hohe Temperaturen sowie starke Magnetfelder schränken die Beobachtbarkeit des Prozesses in der Hall-Héroult-Zelle stark ein. Die oben genannten Ziele können daher allenfalls ansatzweise über Messungen erreicht werden. Ein numerisches Modell zur Untersuchung des Einflusses verschiedener Zellparameter, bietet hier mehrere Vorteile ohne dabei die industrielle Produktion zu beeinträchtigen.

Einer der entscheidenden Faktoren für eine stabile und effiziente Produktion ist die thermische Bilanz einer Hall-Héroult-Zelle. In der vorliegenden Arbeit wird ein numerisches Modell, basierend auf dem Multi-Region Framework des OpenFOAM® 4.0 entwickelt, um das elektrische und thermische Verhalten der Zelle zu untersuchen.

Die Simulationsvorhersagen werden mit industriellen Messungen verglichen, um das numerische Modell zu validieren. Im Anschluss wird der Einfluss verschiedener Betriebsparameter auf das elektrische und thermische Verhalten der Zelle untersucht. In dieser Studie werden dazu die folgenden Betriebsparameter variiert: die Menge an Aluminium und Elektrolyt, der Abstand zwischen Anode und Kathode, der Strom durch die Zelle, die Zusammensetzung des Elektrolyts und die Seitenwandkühlung. Der Einfluss dieser Betriebsparameter auf das Verhalten der Zelle wird durch die Analyse der Schwankungen der Dicke der Randkruste, der Elektrolyttemperatur und der ohmschen Spannung bewertet. Die Ergebnisse dieser Arbeit geben einen detaillierten Einblick in das thermoelektrische Verhalten der Zelle und zeigen kritische Parameter auf, die einen großen Einfluss auf die Produktionseffizienz haben.
