# Abstract

This thesis provides novel concepts and performance evaluations for enhancing the personal safety in industrial plants and during rescue operations of fire brigades and technical emergency services by deploying wireless sensor services. In order to detect sources of danger more precisely and to generate a holistic operational picture of the incident scene, not only infrastructure components will be equipped with sensors; the concept of this thesis foresees the application of wireless connected environmental and vital sensors among employees and emergency personnel. As the focus of this thesis is aligned on safety critical applications, the end users of the system require high precise position information of measured sensor values, high reliability, robustness and availability even under extreme operational conditions.

The goal of this thesis is the design and performance evaluation of selected components for a mobile communication system for sensor-based monitoring, localization and alarming. The special contribution of this thesis is the presentation and detailed validation of solution approaches that enable to address scenarios with exceedingly challenging requirements.

This objective is particularly addressed in the first reference scenario by avoiding explosions in an industrial underground plant, where -due to the hostile environment- new algorithms for RF-based indoor localization have been developed. The evaluation has been accomplished by detailed simulation models and extensive measurement campaigns in the application scenario. It has been demonstrated that the newly developed algorithms enhance the achievable positioning accuracy by almost 90% by reducing the self-interference effects of the system.

On the basis of a second reference scenario -a wide-area forest fire, which is not covered by public cellular networks- a new approach for transmitting text and sensor data over the GALILEO satellite system has been designed and specified. Based on an own developed stochastic simulation model of the satellite system and on analytical modeling for the expected latency, results of the optimization for a low-latency, worldwide available emergency service are provided.

A basic component of both solution approaches is local wireless communication technology operating in the 2.4GHz band, where coexistence interference within the system setup and also with neighboring networks occurs. Therefore, this thesis presents a comprehensive study on the interference behavior especially for the robust IEEE802.15.4a-CSS<sup>1</sup> standard, which is also used for indoor localization.

For rounding up the system design, a comprehensive routing concept has been developed by utilizing redundant connections for building up a new network topology in case of node failures. Furthermore, a novel concept for a Geo- and speech-based alarming service is presented, which can be used for controlling the rescue personal in both application scenarios.

The presented solutions of this thesis have been developed within and contributed to research projects, where industrial partners are involved. The developed system solutions have been validated by end users within the BMWi<sup>2</sup> project *Galileo4FireBrigades* by the fire brigades Dortmund and in the BMBF<sup>3</sup> project *SAVE*<sup>4</sup> by an operator of a huge industrial plant in practical operation. With more than 20 publications in international conferences and contributions to international journals, a broad resonance has been achieved. The results of the research will be included in various future projects, including the Collaborative Research Center SFB876 and a BMWi EXIST Research Transfer project.

# Kurzfassung

Die Personensicherheit in Industrieanlagen sowie bei Rettungseinsätzen von Feuerwehren und technischen Hilfsdiensten kann durch den Einsatz von Sensorsystemen stark gesteigert werden. Zur Detektion von Gefahren aller Art und Erlangung eines umfassenden Lagebilds sollen zunehmend nicht nur die Infrastruktur mit Sensoren ausgestattet werden, sondern auch Personen wie Mitarbeiter und Rettungskräfte mit drahtlos vernetzter Umgebungs- und Vitalsensorik. Für die Anwender ist dabei die hochgenaue Ortsreferenzierung der gewonnenen Informationen sowie die hohe Zuverlässigkeit, Robustheit und Verfügbarkeit des Gesamtsystems auch unter extremen Einsatzbedingungen essentiell.

Das Ziel dieser Arbeit ist der Entwurf und die Leistungsbewertung ausgewählter Komponenten eines mobilen Kommunikationssystems zur Sensor-basierten Messung, Lokalisierung und Alarmierung.

Der besondere Beitrag liegt dabei in der Vorstellung und umfassenden Validierung von Lösungsansätzen, die es ermöglichen, Szenarien mit besonders herausfordernden Anforderungen zu adressieren. Dies ist zum einen die Explosionsvermeidung in einer unterirdischen Industrieanlage, in der durch die feindliche Umgebung neuartige Verfahren für eine Lokalisierung der Mitarbeiter in einem Störfall entwickelt werden mussten. Die Evaluierung der neu entwickelten Verfahren konnte durch detaillierte Simulationsmodelle und umfangreiche Messungen in dem realen Szenario durchgeführt werden. Es konnte hier gezeigt werden, dass durch die neu entwickelten Algorithmen (z.B. zur Reduktion der Eigeninterferenzen) die Genauigkeit der Lokalisierung bei gleichbleibenden Systemkosten um bis zu 90% erhöht werden konnte. Auf der Basis eines weiteren Referenzszenarios, einem großflächigem Waldbrand in einem nicht durch terrestrische Funksysteme erschlossenen Gebiet, wurde in der Arbeit ein neuartiges Verfahren zur Übertragung von Notfallnachrichten mit dem Satellitennavigationssystem GALILEO entwickelt und spezifiziert. Auf der Basis eines eigens entwickelten, stochastischen Satellitenkommunikationsmodells, wie auch durch analytische Modellierung der Latenz, werden Ergebnisse einer Validierung sowie der optimierten Dimensionierung eines weltweit, mit sehr kurzen Verzögerungszeiten einsetzbaren, Notrufdienstes vorgestellt.

Eine wesentliche Basiskomponente beider Lösungsansätze sind lokale Funknetztechniken, die im 2,4 GHz-Band betrieben werden und sich gegenseitig stören sowie durch benachbarte Netze gestört werden. In dieser Arbeit wird daher eine Analyse der Interferenzeinflüsse auch unter Berücksichtigung des als besonders robust ausgewiesenen IEEE802.15.4a-CSS<sup>1</sup> Standards vorgestellt. Zur Abrundung des Systemdesigns wurden Routing Aspekte untersucht, um redundante Verbindungen bei Komponentenausfällen zum Aufbau einer neuen Netztopologie zu nutzen. Weiterhin wurde ein neuartiges Konzept für einen geo- und sprach-basierten Alarmierungsdienst erarbeitet, der in beiden Anwendungsszenarien für die zentrale Steuerung der Einsatzkräfte eingesetzt werden kann. Die in der Arbeit vorgestellten Forschungsergebnisse haben Eingang gefunden in Verbundprojekte, in denen neben Industriepartnern auch Anwender aktiv beteiligt waren. So konnten die entwickelten Systemkonzepte im BMWi<sup>2</sup> Projekt Galileo4Firebrigades durch eine Feuerwehr und im BMBF<sup>3</sup> Projekt SAVE<sup>4</sup> durch einen Betreiber einer sehr großen Industrieanlage auch im praktischen Betrieb validiert werden.

Durch über 20 Veröffentlichungen auf internationalen Konferenzen bzw. Beiträgen zu internationalen Journals konnte eine breite Resonanz erzielt werden. Die Ergebnisse der Forschung werden in Zukunft in verschiedene Folgeprojekte einfließen, unter anderem im Sonderforschungsbereich 876 und einem BMWi-EXIST-Forschungstransferprojekt.
